Finiteness in Cubical Type Theory

ANONYMOUS AUTHOR(S)

We study five different notions of finiteness in Cubical Type Theory and prove the relationship between them. In particular we show that any totally ordered Kuratowski finite type is manifestly Bishop finite.

We also prove closure properties for each finite type, and classify them topos-theoretically. This includes a proof that the category of decidable Kuratowski finite sets (also called the category of cardinal finite sets) form a Π-pretopos.

We then develop a parallel classification for the countably infinite types, as well as a proof of the countability of $A^\star$ for a countable type A.

We formalise our work in Cubical Agda, where we implement a library for proof search (including combinators for level-polymorphic fully generic currying). Through this library we demonstrate a number of uses for the computational content of the univalence axiom, including searching for and synthesising functions.

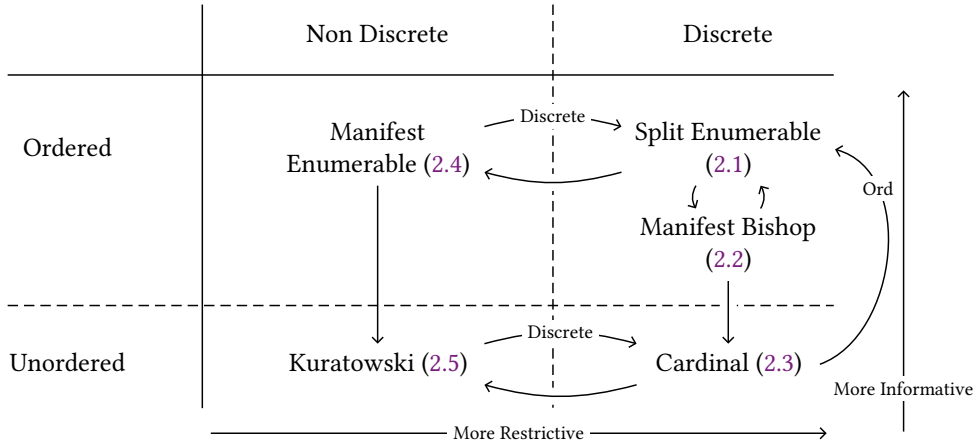

Fig. 1. Classification of finiteness predicates according to whether they are discrete (imply decidable equality) and whether they imply a total order.

1 INTRODUCTION

1.1 Foreword

Foreword

1.2 Contributions

We are interested in constructive notions of finiteness, formalised in Cubical Type Theory [Cohen et al. 2016]. In this paper we will explore five such notions of finiteness, including their categorical interpretation, and use them to build a simple proof-search library facilitated in a fundamental way by univalence. Along the way we will use the Countdown problem [Hutton 2002] as an example, and provide a program which produces verified solutions to the puzzle. We will also briefly examine countability, and demonstrate its parallels and differences with finiteness.

1.2.1 The Varieties of Finiteness. In Section 2 we will explore a number of different predicates for finiteness. In contrast to classical finiteness, in a constructive setting there is a wide variety of predicates which all have some claim to being the formal interpretation of "finiteness" [Coquand and Spiwack 2010]. The particular predicates we are interested in are organised in Figure 1: each arrow in the diagram represents a proof that one predicate can be derived from another.

These finiteness predicates differ along two main axes: informativeness, and restrictiveness. More "informative" predicates have proofs which contain extraneous information other than the finiteness of the underlying type: a proof of split enumerability (Section 2.1), for instance, comes with a strict total order on the underlying type. We will prove that a more informative finiteness predicate can be derived from a less informative one by providing the missing information (Theorem 17).

The "restrictiveness" of a predicate refers to how many types it admits into its notion of "finite". There are strictly more Kuratowski finite (Section 2.5) types than there are Cardinally finite (Section 2.3). We will prove that we can always derive the less restrictive predicate from the more restrictive one, and that we can go in the other direction by satisfying the missing requirement (decidable equality in all of these cases).

Proofs coming with extra information is a common theme in constructive mathematics: often this extra information is in the form of an algorithm which can do something useful related to the

proof itself. Indeed, our proofs of finiteness here will provide an algorithm to solve the countdown puzzle. Occasionally, however, the extra information is undesirable: we may want to assert the existence of some value $x : A$ which satisfies a predicate P without revealing *which* A we're referring to. More concretely, we will need in this paper to prove that two types are in bijection without specifying a particular bijection. This facility is provided by Homotopy Type Theory [Univalent Foundations Program 2013] in the form of propositional truncation, and it is what allows us to prove the bulk of propositions in this paper.

For each predicate we will also prove its closure properties (i.e. that the product of two finite sets is finite). The most significant of these closure proofs is that of closure under Π (dependent functions) (Theorem 11).

1.2.2 Toposes and Finite Sets. In Section 3, we will explore the categorical interpretation of decidable Kuratowski finite sets. The motivation here is partially a practical one: by the end of this work we will have provided a library for proof search over finite types, and the "language" of a topos is a reasonable choice for a principled language for constructing proofs of finiteness in the style of QuickCheck [Claessen and Hughes 2011] generators.

Theoretically speaking, showing that sets in Homotopy Type Theory form a topos (with some caveats) is an important step in characterising the categorical implications of Homotopy Type Theory, first proven in [Rijke and Spitters 2015]. Our work is a formalisation of this result (and the first such formalisation that we are aware of). The proof that decidable Kuratowski finite sets form a Π-pretopos is additional to that.

1.2.3 Countability Predicates. After the finite predicates, we will briefly look at the infinite countable types, and classify them in a parallel way to the finite predicates (Section 4). We will see that we lose closure under function arrows, but we gain it under the Kleene star (Theorem 29).

1.2.4 Search. All of our work is formalised in Cubical Agda [Vezzosi et al. 2019]: as a result, the constructive interpretation of each proof is actually a program which can be run on a computer. In finiteness in particular, these programs are particularly useful for exhaustive search.

We will use the countdown problem as a running example throughout the paper: we will show how to prove that any given puzzle has a finite number of solutions, and from that we will show how to enumerate those solutions, thereby solving the puzzle in a verified way.

In Section 5 we will package up the "search" aspect of finiteness into a library for proof search: similar libraries have been built in [Frumin et al. 2018] and [Firsov and Uustalu 2015]. Our library differs from those in three important ways: firstly, it is strictly more powerful, as it allows for search over function types. Secondly, finiteness proofs also provide equivalence proofs to any other finite type: this allows transport of proofs between types of the same cardinality. Finally, through generic programming we provide a simple syntax for stating properties which mimics that of QuickCheck. We also ground the library in the theoretical notions of omniscience.

1.3 Countdown

Countdown is a well-known functional programming puzzle (later turned into a TV show in the UK), first popularised as a puzzle in which to demonstrate functional algorithms in [Hutton 2002]. As a running example in this paper, we will produce a verified program which lists all solutions to a given countdown puzzle: here we will briefly explain the game and our strategy for solving it.

The idea behind countdown is simple: given a list of numbers, contestants must construct an arithmetic expression (using a small set of functions) using some or all of the numbers, to reach

some target. Here's an example puzzle:

1	3	7	10	25	50

765	(Target)

We'll allow the use of ×, +, and −. The answer is at the bottom of this page[1].

Our strategy for finding solutions to a given puzzle is to describe precisely the type of solutions to a puzzle, and then show that that type is finite. So what is a "solution" to a countdown puzzle? Broadly, it has two parts:

A Transformation from a list of numbers to an expression.
A Predicate showing that the expression is valid and evaluates to the target.

The first part is described in Figure 2.

This transformation has four steps. First (Fig. 2a) we have to pick which numbers we include in our solution. The representation of this transformation should be fairly simple: to pick from n objects we can have an n-tuple of booleans.

Secondly (Fig. 2b) we have to permute the chosen numbers. The representation for a permutation is a little trickier to envision: proving that it's finite is trickier still. We will need to rely on some of the more involved lemmas later on for this problem.

The third step (Fig. 2c) is quite like the first: it's just another n-tuple of finite objects (in this case operators chosen from +, ×, −, and ÷). Although it is complicated slightly by the fact that the n in this n-tuple is dependent on the number of trues in the previously chosen tuple of booleans (in terms of types, that means we'll need a Σ rather than a ×, explanations of which are forthcoming).

Finally (Fig. 2d), we have to parenthesise the expression in a certain way. This can be encapsulated by a binary tree with a certain number of leaves: proving that that is finite is tricky again.

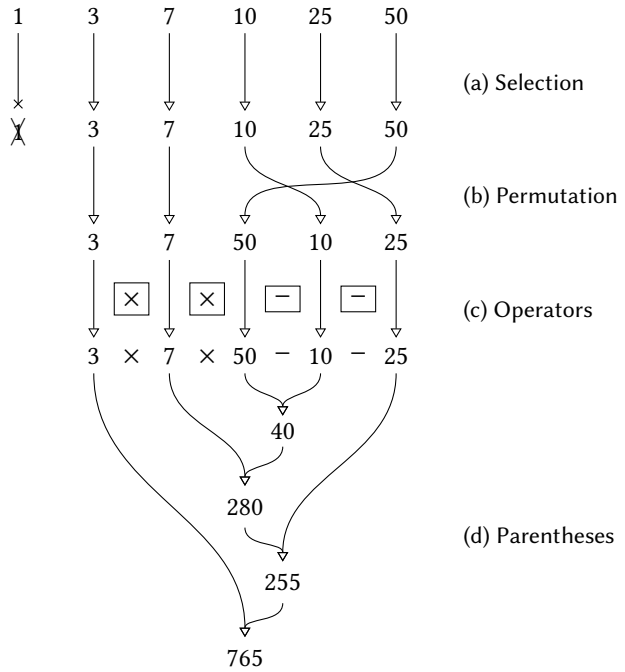

Fig. 2. The components of a transformation which makes up a Countdown candidate solution

Once we have proven that there are finitely many transformations for a list of numbers, we will then have to filter them down to those transformations which are valid, and evaluate to the target. This amounts to proving that the decidable subset of a finite set is also finite.

Finally, we will also want to optimise our solutions and solver: for this we will remove equivalent expressions, which can be accomplished with quotients.

[1] Answer: $3 \times (7 \times (50 - 10) - 25)$

1.4 Notation and Background

We work in Cubical Type Theory [Cohen et al. 2016], specifically Cubical Agda [Vezzosi et al. 2019]. Cubical Agda is a dependently-typed functional programming language, based on Martin-Löf Intuitionistic Type Theory, with a Haskell-like syntax.

Being a dependently-typed language, we'll have to be clear about what we mean when we say "type" in Agda.

Definition 1 (Type)**.** We use Type to denote the universe of (small) types. The universe level is denoted with a subscript number, starting at 0. "Type families" are functions into Type.

The are two broad ways to define types in Agda: as an inductive **data** type, similar to data type definitions in Haskell, or as a **record**. Here we'll define the basic type formers used in MLTT.

Definition 2 (Basic Types)**.** The three basic types—often called 0, 1, and 2 in MLTT—here will be denoted with their more common names: $\bot$, $\top$, and **Bool**, respectively.

```
data ⊥ : Type₀ where
```

```
record ⊤ : Type₀ where
  constructor tt
```

```
data Bool : Type₀ where
  true  : Bool
  false : Bool
```

Definition 3 (The Dependent Sum)**.** Dependent sums are denoted with the usual Σ symbol, and has the following definition in Agda:

```
record Σ (A : Type a) (B : A → Type b) : Type (a ℓ⊔ b) where
  constructor _,_
  field
    fst : A
    snd : B fst
```

We will use different notations to refer to this type depending on the setting. The following four expressions all denote the same type:

```
Σ A B
```

```
∃ B
```

```
Σ[ x : A ] B x
```

```
∃[ x ] B x
```

The non-dependent product is a special instance of the dependent. We indicate a simple pair of types A and B as $A \times B$.

Definition 4 (Dependent Product)**.** Dependent products (dependent functions) use the Π symbol.

The three following expressions all denote the same type:

```
Π A B
```

```
(x : A) → B x
```

```
∀ x → B x
```

Again, the non-dependent case is a special case of the dependent case. Non-dependent functions are denoted with the arrow ($\rightarrow$).

Definition 5 (Disjoint Union)**.** We define disjoint union as an inductive type.

```
data _⊎_ (A : Type a) (B : Type b) : Type (a ℓ⊔ b) where
  inl : A → A ⊎ B
  inr : B → A ⊎ B
```

It is also expressible with only Σ:

```
_⊎_ : Type a → Type a → Type _
A ⊎ B = Σ[ x : Bool ] if x then A else B
```

Definition 6 (Equalities, equivalences, and paths)**.** $\simeq$ will be used for equivalences, and $\equiv$ for equalities. Of course, we know that $(A \simeq B) \simeq (A \equiv B)$ by univalence, so the distinction isn't terribly important in usage: we will only use one or the other as a suggestion of how we constructed it or how it is to be used.

Definition 7 (Path Types)**.** The equality type (which we denote with $\equiv$) in CuTT is the type of Paths[2]. The internal structure of paths is largely irrelevant to us here, as we will generally treat $\equiv$ as a black-box equivalence relation with substitution and congruence.

Definition 8 (Homotopy Levels)**.** Types in HoTT and CuTT are not necessarily sets, as they are in MLTT. Some have higher homotopies (paths which aren't unique). We actually have a hierarchy of complexity of structure of path spaces in types, starting with the contractions [Univalent Foundations Program 2013, definition 3.11.1], then the mere propositions [Univalent Foundations Program 2013, definition 3.3.1], and the sets [Univalent Foundations Program 2013, definition 3.1.1].

```
isContr A = Σ[ x : A ] ∀ y → x ≡ y
isProp  A = (x y : A) → x ≡ y
isSet   A = (x y : A) → isProp (x ≡ y)
```

Definition 9 (Fibers)**.** A fiber [Univalent Foundations Program 2013, definition 4.2.4] is defined over some function $f : A \to B$.

```
fiber : (A → B) → B → Type _
fiber f y = ∃[ x ] (f x ≡ y)
```

Definition 10 (Equivalences)**.** We will take contractible maps [Univalent Foundations Program 2013, definition 4.4.1] as our "default" definition of equivalences.

$$\text{isEquiv}(f) \coloneqq \Pi(y : B), \text{isContr}(\text{fib}_f(y)) \tag{1}$$

$$A \simeq B \coloneqq \Sigma(f : A \to B), \text{isEquiv}(f) \tag{2}$$

Definition 11 (Decidable Types)**.**

$$\mathbf{Dec}(A) \coloneqq A \uplus \neg A \tag{3}$$

Definition 12 (Discrete Types)**.** A discrete type is one with decidable equality.

$$\text{Discrete}(A) \coloneqq \Pi(x, y : A), \mathbf{Dec}(x \equiv y) \tag{4}$$

By Hedberg's theorem [Hedberg 1998] any discrete type is a set.

Definition 13 (Higher Inductive Types)**.** Normal inductive types have *point* constructors: constructors which construct values of the type. Higher Inductive Types (HITs) also have *path* constructors: ways to construct paths in the type.

[2] Actually, CuTT does have an identity type with similar semantics to the identity type in MLTT. We do not use this type anywhere in our work, however, so we will not consider it here.

Definition 14 (Propositional Truncation)**.** The type $\|A\|$ on some type A is a propositionally truncated proof of A [Univalent Foundations Program 2013, 3.7]. In other words, it is a proof that some A exists, but it does not tell you *which* A.

It is defined as a Higher Inductive Type:

$$\begin{aligned} \|A\| \coloneqq |\cdot| \quad &: A \to \|A\|; \\ \mid \text{squash}: &\Pi(x, y : \|A\|), x \equiv y; \end{aligned} \tag{5}$$

We will use two eliminators from $\|A\|$ in this paper.

(1) For any function $A \to B$, where $\text{isProp}(B)$, we have a function $\|A\| \to B$.
(2) We can eliminate from $\|A\|$ with a function $f : A \to B$ iff f "doesn't care" about the choice of A:

$$\Pi(x, y : A), f(x) \equiv f(y)$$

Formally speaking, f needs to be "coherently constant" [Kraus 2015], and B needs to be an n-type for some finite n.

2 FINITENESS PREDICATES

In this section, we will define and briefly describe each of the five predicates in Figure 1. As we will see, each of these predicates has subtle differences from the others: we will outline how some predicates are too informative, and how others aren't powerful enough, for our needs, before settling on decidable Kuratowski finiteness as our focus.

As we make our way through each predicate, we will be interested in two aspects: how can we build proofs of this predicate (i.e. is the product of two finite types finite?) and what do we *get* once we do (i.e. does this predicate tell us the number of elements in the finite set?).

2.1 Split Enumerability

We will start with a simple notion of finiteness, called *split* enumerability.

Definition 15 (Split Enumerable Set)**.** To say that some type A is split enumerable is to say that there is a list $support : \mathbf{List}(A)$ such that any value $x : A$ is in $support$.

$$\mathcal{E}!(A) \coloneqq \Sigma(support : \mathbf{List}(A)), \Pi(x : A), x \in support \tag{6}$$

We call the first component of this pair the "support" list, and the second component the "cover" proof. An equivalent version of this predicate was called `Listable` in [Firsov and Uustalu 2015].

We used some extra types in the above definition, which we will define here:

Definition 16 (List). In this paper we define lists as *containers*:

$$\mathbf{List} \coloneqq [\![\mathbb{N}, \mathbf{Fin}]\!] \tag{7}$$

This may seem quite foreign or complex in comparison to the usual definition of lists as an inductive data type:

$$\begin{aligned} \mathbf{List}(A) \coloneqq\ & [] \quad : && \mathbf{List}(A); \\ & \mid \cdot :: \cdot : A \to \mathbf{List}(A) \to \mathbf{List}(A); \end{aligned} \tag{8}$$

But it turns out to be quite useful for later proofs.

Moreover, the inductive type and the container-based type are equivalent, as is proven in our formalisation.

Definition 17 (Containers)**.** A container [Abbott et al. 2005] is a pair S, P where S is a type, the elements of which are called the *shapes* of the container, and P is a type family on S, where the elements of $P(s)$ are called the *positions* of a container. We "interpret" a container into a functor defined like so:

$$[\![S, P]\!](A) \coloneqq \Sigma(s : S), (P(s) \to A) \tag{9}$$

Membership of a container can be defined like so:

$$x \in xs \coloneqq \mathrm{fib}_{\mathrm{snd}(xs)}(x) \tag{10}$$

Definition 18 (Fin). $\mathbf{Fin}(n)$ is the type of natural numbers smaller than n. We define it the standard way:

$$\begin{aligned} \mathbf{Fin}(0) &\coloneqq \bot; \\ \mathbf{Fin}(n+1) &\coloneqq \top \uplus \mathbf{Fin}(n); \end{aligned} \tag{11}$$

2.1.1 Instances. Now that we have a suitable definition of finiteness, we will next prove that some things are finite.

Lemma 1. $\bot$, $\top$, and **Bool** are split enumerable.

Proof. These three types are represented by fairly simple finite sets:

$$\bot = \{\} \tag{12}$$

$$\top = \{\mathrm{tt}\} \tag{13}$$

$$\mathbf{Bool} = \{\mathrm{false}, \mathrm{true}\} \tag{14}$$

Which leads to quite simple proofs of finiteness.

The support list for is [], [tt], and [false, true], respectively, and the cover proof is a function that returns the index of the supplied element. ■

The code in our formalisation of these three proofs is quite simple. Just as an example, the proof that **Bool** is split enumerable is as follows:

```
ℰ!⟨2⟩ : ℰ! Bool
ℰ!⟨2⟩ .fst = [ false , true ]
ℰ!⟨2⟩ .snd false = 0 , refl
ℰ!⟨2⟩ .snd true  = 1 , refl
```

With the most basic simple types out of the way, the obvious next choice is the (non-dependent) sums and products: $\uplus$ and $\times$. Both of these types can be constructed from the *dependent* sum, however, so that is the type we will prove finite. From that we can derive a much wider array of finiteness proofs.

Lemma 2. Split enumerability is closed under Σ.

$$\frac{\mathcal{E}!(A) \quad \Pi(x : A), \mathcal{E}!(U(x))}{\mathcal{E}!(\Sigma(x : A), U(x))} \tag{15}$$

Proof. Let A be a type which is split enumerable, and U be a type family over A which is split enumerable at every point. Formally, we have the following proofs:

$$\mathcal{E}!_A : \mathcal{E}!(A) \tag{16}$$

$$\mathcal{E}!_U : \Pi(x : A), \mathcal{E}!(U(x)) \tag{17}$$

Our task is to construct a proof of type:

$$\mathcal{E}!(\Sigma(x : A), U(x)) \tag{18}$$

This proof itself is composed of two components:

$$\mathit{support} : \mathbf{List}(\Sigma(x : A), U(x)) \tag{19}$$

$$\mathit{cover} : \Pi(x : \Sigma(y : A), U(y)), x \in \mathit{support} \tag{20}$$

To construct the support list, we apply the function $\mathcal{E}!_U$ to every element in the support list of $\mathcal{E}!_A$, extract the support lists from the resulting finiteness proofs, and concatenate them.

To prove that this support list does in fact cover the entirety of the type $\Sigma\ A\ U$, we note that any element of type $\Sigma\ A\ U$ must have a first component in the support list of $\mathcal{E}!_A$, and its second component must be in the result of applying $\mathcal{E}!_U$ to that first element (since that support list contains every element of type $U(x)$). Therefore, the pair itself must be in our constructed support list. ■

This pattern of applying a function to each element in a list and concatenating the result is of course well-known in functional programming, and is in fact the pattern that makes lists a monad. While this insight isn't strictly relevant to our work here, it does mean the implementation of this function can use Agda's do notation, resulting in the following extremely clean implementation:

```
sup-Σ : List A →
        Π[ x : A ] List (U x) →
        List (Σ A U)
sup-Σ xs ys = do x ← xs
                 y ← ys x
                 [ x , y ]
```

2.1.2 Derivations. We have a way to construct finiteness proofs, and a semiring-like toolbox to combine them. What we're now interested in is what we can *derive* from them.

First, we will look at how this predicate relates to more traditional, classical notions of finiteness. in a classical setting we likely wouldn't mention "lists" or the like, and would instead define finiteness based on the existence of some injection or surjection. As it turns out, our definition of finiteness here is precisely the same as the surjection-based one, in quite a deep way!

First, we will need to define our terms: in HoTT, surjections are a little more complex than what you'd find in either MLTT or classical mathematics.

Definition 19 (Surjections)**.** We define both surjections and *split* surjections here [Univalent Foundations Program 2013, definition 4.6.1].

$$\begin{aligned}
\mathrm{surj}(f) &:= \Pi(y : B), \|\mathrm{fib}_f(y)\| && (21)\\
A \twoheadrightarrow B &:= \Sigma(f : A \to B), \mathrm{surj}(f) && (22)\\
\text{sp-surj}(f) &:= \Pi(y : B), \mathrm{fib}_f(y) && (23)\\
A \twoheadrightarrow! B &:= \Sigma(f : A \to B), \text{sp-surj}(f) && (24)
\end{aligned}$$

Over sets, the surjections and split surjections are the same thing, but there is a difference one we involve non-set types like the circle.

We will now see that split enumerability is in fact a split surjection in another form:

Lemma 3. A proof of split enumerability is equivalent to a split surjection from a finite prefix of the natural numbers.

$$\mathcal{E}!(A) \simeq \Sigma(n : \mathbb{N}), (\mathbf{Fin}(n) \twoheadrightarrow! A) \tag{25}$$

Proof.

$$\begin{aligned}
\mathcal{E}!(A) &\simeq \Sigma(xs : \mathbf{List}(A)), \Pi(x : A), x \in xs && \text{def. 15 } (\mathcal{E}!)\\
&\simeq \Sigma(xs : \mathbf{List}(A)), \Pi(x : A), \mathrm{fib}_{\mathrm{snd}(xs)}(x) && \text{eqn. 10 } (\in)\\
&\simeq \Sigma(xs : \mathbf{List}(A)), \text{sp-surj}(\mathrm{snd}(xs)) && \text{eqn. 23 (sp-surj)}\\
&\simeq \Sigma(xs : [\![\mathbb{N}, \mathbf{Fin}]\!](A)), \text{sp-surj}(\mathrm{snd}(xs)) && \text{def. 16 (\textbf{List})}\\
&\simeq \Sigma(xs : \Sigma(n : \mathbb{N}), \Pi(i : \mathbf{Fin}(n)), A), \text{sp-surj}(\mathrm{snd}(xs)) && \text{eqn. 9 } ([\![\cdot]\!])\\
&\simeq \Sigma(n : \mathbb{N}), \Sigma(f : \mathbf{Fin}(n) \to A), \text{sp-surj}(f) && \text{Reassociation of } \Sigma\\
&\simeq \Sigma(n : \mathbb{N}), (\mathbf{Fin}(n) \twoheadrightarrow! A) && \text{eqn. 24 } (\twoheadrightarrow!) \ \blacksquare
\end{aligned}$$

In our formalisation, the proof is a single line:
```
ℰ!⇔Fin↠! = reassoc
```
The only step which isn't definitional equality is the reassociation of Σ.
```
reassoc :
  Σ (Σ A B) C ⇔
  Σ[ x : A ] Σ[ y : B x ] C (x , y)
```

(The simplicity of this proof, by the way, is why we preferred the container-based definition of lists over the traditional one.)

Split enumerability implies decidable equality on the underlying type. To prove this, we will make use of the following lemma, proven in the formalisation:

Definition 20 (Injections)**.** Injective functions are more straightforward to define constructively than surjective ones:

$$\text{injective}(f) \coloneqq \Pi(x, y : A), f\ x \equiv f\ y \to x \equiv y \tag{26}$$

$$A \rightarrowtail B \quad \coloneqq \Sigma(f : A \to B), \text{injective}(f) \tag{27}$$

Lemma 4. A split-surjection from A to B implies an injection from B to A.

$$(A \twoheadrightarrow! B) \to (B \rightarrowtail A) \tag{28}$$

Lemma 5. For any type A which injects into a discrete type B, A is discrete.

$$\frac{A \rightarrowtail B \quad \text{Discrete}(B)}{\text{Discrete}(A)} \tag{29}$$

Lemma 6.

$$\frac{A \twoheadrightarrow! B \quad \text{Discrete}(A)}{\text{Discrete}(B)} \tag{30}$$

Proof. This proof is can be straightforwardly derived from lemmas 4 and 5. ■

Lemma 7. Every split enumerable type is discrete.

Proof. Let A be a split enumerable type. By lemma 3, there is a surjection from $\mathbf{Fin}(n)$ for some n. Also, we know that $\mathbf{Fin}(n)$ is discrete (proven in our formalisation). Therefore, by lemma 6, A is discrete. ■

2.2 Manifest Bishop Finiteness

We mentioned in the introduction that occasionally in constructive mathematics proofs will contain "too much" information. With split enumerability we can see an instance of this.

Consider the following proof of the finiteness of Bool:
```
ℰ!⟨2⟩ : ℰ! Bool
ℰ!⟨2⟩ .fst = [ false , true , false ]
ℰ!⟨2⟩ .snd false = 0 , refl
ℰ!⟨2⟩ .snd true  = 1 , refl
```
While it represents the "same" information as our previous proof, it is clearly not the same *object*.

There is "slop" in the type of split enumerability: there are more distinct values than there are *usefully* distinct values. As we can see in the example above, for instance, split enumerability allows duplicate values in the support list. To reconcile this, we will disallow duplicates in the support list.

How exactly we should do this is the next question. One approach might be to change the definition of **List**, or introduce a new type **NoDupeList**, and use it in the predicate instead. However, this would mean we lose access to the functions we have defined on lists, and we have to change the definition of $\in$ as well.

There is a much simpler and more elegant solution: we insist that every *membership proof* must be unique. This would disallow a definition of $\mathcal{E}!(\mathbf{Bool})$ with duplicates, as there are multiple values which inhabit the type false $\in$ [false, true, false]. It also allows us to keep most of the split enumerability definition unchanged, just adding a condition to the returned membership proof in the cover proof.

To specify that a value must exist uniquely in HoTT we can use the concept of a *contraction*.

Definition 21 (Unique Membership)**.** Unique list membership is defined in terms of list membership: it is a contraction of it.

$$x \in! \; xs \coloneqq \text{isContr}(x \in xs) \tag{31}$$

With this we can define manifest Bishop finiteness:

Definition 22 (Manifest Bishop Finiteness)**.** A type is manifest Bishop finite if there exists a list which contains each value in the type once.

$$\mathcal{B}(A) \coloneqq \Sigma(xs : \mathbf{List}(A)), \Pi(x : A), x \in! \; xs \tag{32}$$

The only difference between manifest Bishop finiteness and split enumerability is the membership term: here we require unique membership ($\in!$), rather than simple membership ($\in$).

We use the word "manifest" here to distinguish from another common interpretation of Bishop finiteness, which we have called cardinal finiteness in this paper. The "manifest" refers to the fact that we have a concrete, non-truncated list of the elements in the proof.

2.2.1 The Relationship Between Manifest Bishop Finiteness and Split Enumerability. While manifest Bishop finiteness might seem stronger than split enumerability, it turns out this is not the case. Both predicates imply the other.

Lemma 8. Any manifest Bishop finite type is split enumerable.

Proof. To construct a proof of split enumerability from one of manifest Bishop finiteness, it suffices to convert a proof of $x \in! \; xs$ to one of $x \in xs$, for all x and xs. Since $\in!$ is defined as a contraction of $\in$, such a conversion is simply the fst function. ■

Lemma 9. Any split enumerable set is manifest Bishop finite.

This proof takes significantly more work. The "unique membership" condition in $\mathcal{B}$ means that we are not permitted duplicates in the support list. The first step in the proof, then, is to filter those duplicates out from the support list of the $\mathcal{E}!$ proof: we can do this using the decidable equality provided by $\mathcal{E}!$ (lemma 7). From there, we need to show that the membership proof carries over appropriately.

Provide more info on this proof?

We have now proved that every manifestly Bishop finite type is split enumerable, and vice versa. While the types are not *equivalent* (there are more split enumerable proofs than there are manifest Bishop finite proofs), they are of equal power, so any closure proof we have on one can be transferred to the other. In particular, it means that manifest Bishop finiteness is closed under Σ.

2.2.2 From Manifest Bishop Finiteness to Equivalence. We have seen that split enumerability was in fact a split-surjection in disguise. We will now see that manifest Bishop finiteness is in fact an *equivalence* in disguise. *equivalence* with **Fin**.

Lemma 10. Manifest bishop finiteness is equivalent to an equivalence to a finite prefix of the natural numbers.

$$\mathcal{B}(A) \simeq \Sigma(n : \mathbb{N}), (\mathbf{Fin}(n) \simeq A) \tag{33}$$

Proof.

$$\begin{aligned}
\mathcal{B}(A) &\simeq \Sigma(xs : \mathbf{List}(A)), \Pi(x : A), x \in! \ xs && \text{def. 22 } (\mathcal{B}) \\
&\simeq \Sigma(xs : \mathbf{List}(A)), \Pi(x : A), \mathrm{isContr}(x \in xs) && \text{eqn. 21 } (\in!) \\
&\simeq \Sigma(xs : \mathbf{List}(A)), \Pi(x : A), \mathrm{isContr}(\mathrm{fib}_{\mathrm{snd}(xs)}(x)) && \text{eqn. 10 } (\in) \\
&\simeq \Sigma(xs : \mathbf{List}(A)), \mathrm{isEquiv}(\mathrm{snd}(xs)) && \text{eqn. 1 (isEquiv)} \\
&\simeq \Sigma(xs : [\![\mathbb{N}, \mathbf{Fin}]\!](A)), \mathrm{isEquiv}(\mathrm{snd}(xs)) && \text{def. 16 (\textbf{List})} \\
&\simeq \Sigma(xs : \Sigma(n : \mathbb{N}), \Pi(i : \mathbf{Fin}(n)), A), \mathrm{isEquiv}(\mathrm{snd}(xs)) && \text{eqn. 9 } ([\![\cdot]\!]) \\
&\simeq \Sigma(n : \mathbb{N}), \Sigma(f : \mathbf{Fin}(n) \to A), \mathrm{isEquiv}(f) && \text{Reassociation of } \Sigma \\
&\simeq \Sigma(n : \mathbb{N}), (\mathbf{Fin}(n) \simeq A) && \text{eqn. 2 } (\simeq) \ \blacksquare
\end{aligned}$$

This proof is almost identical[3] to the proof for lemma 3: it reveals that enumeration-based finiteness predicates are simply another perspective on relation-based ones.

As we are working in CuTT, a proof of equivalence between two types gives us the ability to *transport* proofs from one type to the other. This is extremely powerful, as we will see.

2.2.3 Closure Under Π. The glaring omission from our closure proofs under type formers so far has been the Π type: we have not proved closure under functions, dependent or otherwise. In MLTT, this is of course not provable: since all of the finiteness predicates we have seen so far imply decidable equality, and since we don't have any kind of decidable equality on functions in MLTT, we know that we won't be able to show that any kind of function is finite; even one like $\mathbf{Bool} \to \mathbf{Bool}$.

CuTT is not so restricted. Since we have things like function extensionality and transport, we can indeed prove the finiteness of function types. Our proof here makes use directly of the univalence axiom, and makes use furthermore of all the previous closure proofs. We will prove this closure on split enumerability, rather than on manifest Bishop finiteness, as it requires slightly less legwork in the proof itself, but of course we can derive the proof on manifest Bishop finiteness in a few lines.

Theorem 11. Split enumerability is closed under dependent functions. (Π-types).

$$\frac{\mathcal{E}!(A) \quad \Pi(x : A), \mathcal{E}!\,(U(x))}{\mathcal{E}!\,(\Pi(x : A), U(x))} \tag{34}$$

Proof. Let A be a split enumerable type, and U be a type family from A, which is split enumerable over all points of A.

As A is split enumerable, we know that it is also manifestly Bishop finite (lemma 9), and consequently we know $A \simeq \mathbf{Fin}(n)$, for some n (lemma 10). We can therefore replace all occurrences of A with $\mathbf{Fin}(n)$, changing our goal to:

$$\frac{\mathcal{E}!(\mathbf{Fin}(n)) \quad \Pi(x : \mathbf{Fin}(n)), \mathcal{E}!\,(U(x))}{\mathcal{E}!\,(\Pi(x : \mathbf{Fin}(n)), U(x))} \tag{35}$$

We then define the type of n-tuples over some type family $T : \mathbf{Fin}(n) \to \mathbf{Type}$.

$$\begin{aligned}
\mathbf{Tuple}(0, T) &:= \top \\
\mathbf{Tuple}(n + 1, T) &:= T(0) \times \mathbf{Tuple}(n, T \circ \mathrm{suc})
\end{aligned} \tag{36}$$

[3] Unfortunately in our formalisation this proof cannot be a single line: for performance reasons ≃ is defined as a record type with eta-equality disabled, instead of the definition here which uses Σ.

We can show that this type is equivalent to functions (proven in our formalisation):

$$\Pi(x : \mathbf{Fin}(n)), U(x) \simeq \mathbf{Tuple}(n, U) \tag{37}$$

And therefore we can simplify again our goal to the following:

$$\frac{\mathcal{E}!(\mathbf{Fin}(n)) \quad \Pi(x : \mathbf{Fin}(n)), \mathcal{E}!\,(U(x))}{\mathcal{E}!\,(\mathbf{Tuple}(n, U))} \tag{38}$$

We can prove this goal by showing that $\mathbf{Tuple}(n, U)$ is split enumerable: it is made up of finitely many products of points of U, which are themselves split enumerable, and $\top$, which is also split enumerable. Lemma 2 shows us that the product of finitely many split enumerable types is itself split enumerable, proving our goal. ■

2.3 Cardinal Finiteness

While we have removed some of the unnecessary information from our finiteness predicates, one piece still remains.

The two following proofs are both valid proofs of the finiteness of **Bool**, and both do not include any duplicates. However they still differ:

```
ℰ!⟨2⟩ : ℰ! Bool
ℰ!⟨2⟩ .fst = [ false , true ]
ℰ!⟨2⟩ .snd false = 0 , refl
ℰ!⟨2⟩ .snd true  = 1 , refl

ℰ!⟨2⟩ : ℰ! Bool
ℰ!⟨2⟩ .fst = [ true , false ]
ℰ!⟨2⟩ .snd false = 1 , refl
ℰ!⟨2⟩ .snd true  = 0 , refl
```

Each finiteness predicate so far has contained an *ordering* of the underlying type. For our purposes, this is too much information: it means that when constructing the "category of finite sets" later on, instead of each type having one canonical representative, it will have $n!$, where n is the cardinality of the type[4].

To remedy the problem, we will use propositional truncation (def. 14).

Definition 23 (Cardinal Finiteness)**.** A type A is cardinally finite if there exists a propositionally truncated proof that A is manifest Bishop finite or equivalent to a finite prefix of the natural numbers.

$$C(A) :\equiv \|\mathcal{B}(A)\| \simeq \|\Sigma(n : \mathbb{N}), (\mathbf{Fin}(n) \simeq A)\| \tag{39}$$

At first glance, it might seem that we lose any useful properties we could derive from $\mathcal{B}$. Luckily, this is not the case: by eliminator 2 of def. 14, we need only show that the output is uniquely determined.

[4]We actually do get a category (a groupoid, even) from manifest Bishop finiteness [Yorgey 2014]: it's the groupoid of finite sets equipped with a linear order, whose morphisms are order-preserving bijections. We do not explore this particular construction in any detail.

2.3.1 Deriving Uniquely-Determined Quantities. The following two lemmas are proven in [Yorgey 2014] (Proposition 2.4.9 and 2.4.10, respectively), in much the same way as we have done here. Our contribution for this section is simply the formalisation.

Lemma 12. Given a cardinally finite type, we can derive the type's cardinality, as well as a propositionally truncated proof of equivalence with **Fin**s of the same cardinality.

$$C(A) \to \Sigma(n : \mathbb{N}), \|\mathbf{Fin}(n) \simeq A\| \tag{40}$$

Proof. Let A be a cardinally-finite type, with proof $F : C(A)$. Our task is to extract a natural number $n : \mathbb{N}$ representing the cardinality of A, and a propositionally-truncated proof that A is equivalent to $\mathbf{Fin}(n)$.

Extracting the second component of the pair is trivial, as it itself is truncated. We will now focus on extracting the cardinality.

Without the propositional truncation, fst would suffice for this task. Given that the pair is hidden under the truncation, then, we need a way to convert a function $f : A \to B$ to $g : \|A\| \to B$. This is precisely what eliminator 2 gives us. For our case, we need to show the following:

$$\frac{(n : \mathbb{N}) \quad (p : \mathbf{Fin}(n) \simeq A) \quad (m : \mathbb{N}) \quad (q : \mathbf{Fin}(m) \simeq A)}{n \equiv m} \tag{41}$$

Immediately we can construct the following term:

$$\begin{aligned} \mathbf{Fin}(n) &\simeq A \qquad (p) \\ &\simeq \mathbf{Fin}(m) \qquad (q) \end{aligned} \tag{42}$$

Given univalence we have $\mathbf{Fin}(n) \equiv \mathbf{Fin}(m)$, and the rest of our task is to prove:

$$\frac{\mathbf{Fin}(n) \equiv \mathbf{Fin}(m)}{n \equiv m} \tag{43}$$

This is a well-known chestnut in dependently-typed programming, and one that has a surprisingly tricky and complex proof. We do not include it here, since it has already been explored elsewhere, but it is present in our formalisation. ■

In order to prove that cardinal finiteness implies decidable equality, we will need to show that decidable equality itself is a proposition. In doing that we will use the following lemma:

Lemma 13. We can "refute" a propositionally-truncated proof of some proposition with a proof that the non-truncated proposition is false.

$$\frac{\neg A \quad \|A\|}{\bot} \tag{44}$$

Proof. We know we can eliminate from any value of type $\|A\|$ into some B with a function $A \to B$ if B is a proposition. That's precisely what we do in this case: $\neg A$ is a function of type $A \to \bot$, and we know that $\bot$ is a proposition. ■

Lemma 14. Any cardinal-finite set has decidable equality.

Proof. Since we can already derive decidable equality from a proof of manifest Bishop finiteness, it suffices to show that decidable equality is itself a proposition.

$$\mathrm{isProp}(\Pi(x, y : A), \mathbf{Dec}(x \equiv y)) \tag{45}$$

First, it is clear that $x \equiv y$ is a proposition: since the type A has decidable equality, by Hedburg's theorem it is a set, meaning precisely that $x \equiv y$ is a proposition.

Secondly, we know that any decision over a proposition is itself a proposition. For any two terms $x, y : \mathbf{Dec}(A)$ we cannot have the case that one is a yes decision and the other is no: from that

we could derive $\bot$. If both are no then they are both equal since $A \to \bot$ is a proposition through function extensionality. And finally if both are yes then we know they must be equal because the type decided over is itself a proposition.

Finally, since we know that $\mathbf{Dec}(x \equiv y)$ is a proposition, we can derive that $\Pi(x, y : A), \mathbf{Dec}(x \equiv y)$ is a proposition (through function extensionality), proving our goal. ■

2.3.2 Restrictiveness. So far our explorations into finiteness predicates have pushed us in the direction of "less informative": however, as mentioned in the introduction, we can *also* ask how *restrictive* certain predicates are. Since split enumerability and manifest Bishop finiteness imply each other we know that there can be no type which satisfies one but not the other. We also know that manifest Bishop finiteness implies cardinal finiteness, but we do *not* have a function in the other direction:

$$C(A) \to \mathcal{B}(A) \tag{46}$$

So the question arises naturally: is there a cardinally finite type which is *not* manifest Bishop finite?

It turns out the answer is no!

Lemma 15.

$$\neg(\Sigma(A : \mathbf{Type}), C(A) \times \neg\mathcal{B}(A)) \tag{47}$$

Proof. We will actually prove a slightly more general statement. For any type A, the following holds:

$$\neg(\|A\| \times \neg A) \tag{48}$$

The solution becomes more clear if we write out the definition of $\neg$:

$$\frac{\|A\| \quad A \to \bot}{\bot} \tag{49}$$

We clearly need to apply a function of type $A \to \bot$ to a value of type $\|A\|$. Luckily, this is permissible, as $\bot$ is a mere proposition. ■

2.3.3 Going from Cardinal Finiteness to Manifest Bishop Finiteness.

Lemma 16. Any manifest Bishop finite type is cardinal finite.

Theorem 17. Any cardinal finite type with a total order is Bishop finite.

The proof for this particular theorem is quite involved in the formalisation, so we only give its sketch here. First, note that we actually convert to manifest enumerability first: this can be converted to split enumerability with decidable equality, which is provided by cardinal finiteness.

Next, we define permutations.

Definition 24 (List Permutations)**.** Two lists are permutations of each other if their membership proofs are all equivalent[5][Danielsson 2012].

$$xs \leftrightsquigarrow ys = \Pi(x : A), x \in xs \simeq x \in ys \tag{50}$$

Next, we define a sort function which relies on the provided total order. We further prove the following fact about this sort function:

$$\Pi(xs, ys : \mathbf{List}(A)), xs \leftrightsquigarrow ys \to \mathrm{sort}(xs) \equiv \mathrm{sort}(ys) \tag{51}$$

Next, notice that the support lists of any two proofs of manifest Bishop finiteness must be permutations of each other. This will allow us to sort the support list of a proof of cardinal finiteness in a coherently constant (definition 14, eliminator 2) way, pulling the support list out from the truncation. The cover proof emerges naturally from the definition of the permutation.

[5]The definition in [Danielsson 2012] and our formalisation is slightly different: we say permutations are lists with *isomorphic* membership proofs. The distinction, as it happens, does not affect our work here.

2.3.4 Closure. Since we don't have a function of type $C(A) \to \mathcal{B}(A)$, closure proofs on $\mathcal{B}$ do not transfer over to C trivially (unlike with $\mathcal{E}!$ and $\mathcal{B}$). The cases for $\bot$, $\top$, and **Bool** are simple to adapt: we can just propositionally truncate their Bishop finiteness proof.

Non-dependent operators like $\times$, $\uplus$, and $\to$ are also relatively straightforward: since $\|\cdot\|$ forms a monad, we can apply n-ary functions to values inside it, combining them together.

The fact that $\|\cdot\|$ forms a monad means that we can lift n-ary functions like the following:

```
_|×|_ : ℬ A →
        ℬ B →
        ℬ (A × B)
```

Into a truncated context:

```
_||×||_ : 𝒞 A →
          𝒞 B →
          𝒞 (A × B)
xs ||×|| ys = do
  x ← xs
  y ← ys
  | x |×| y |
```

Unfortunately, for the dependent type formers like Σ and Π, the same trick does not work. We have closure proofs like:

$$\frac{\mathcal{B}(A) \quad \Pi(x : A), \mathcal{B}(U(x))}{\mathcal{B}(\Pi\ A\ U)} \tag{52}$$

If we apply the monadic truncation trick we can derive closure proofs like the following:

$$\frac{\|\mathcal{B}(A)\| \quad \|\Pi(x : A), \mathcal{B}(U(x))\|}{\|\mathcal{B}(\Pi\ A\ U)\|} \tag{53}$$

However our *desired* closure proof is the following:

$$\frac{\|\mathcal{B}(A)\| \quad \Pi(x : A), \|\mathcal{B}(U(x))\|}{\|\mathcal{B}(\Pi\ A\ U)\|} \tag{54}$$

They don't match!

The solution would be to find a function of the following type:

$$(\Pi(x : A), \|\mathcal{B}(U(x))\|) \to \|\Pi(x : A), \mathcal{B}(U(x))\| \tag{55}$$

However we might be disheartened at realising that this is a required goal: the above equation is *extremely* similar to the axiom of choice!

Definition 25 (Axiom of Choice)**.** In HoTT, the axiom of choice is commonly defined as follows [Univalent Foundations Program 2013, lemma 3.8.2]. For any set A, and a type family U which is a set at all the points of A, the following function exists:

$$(\Pi(x : A), \|U(x)\|) \to \|\Pi(x : A), U(x)\| \tag{56}$$

Luckily the axiom of choice *does* hold for cardinally finite types, allowing us to prove the following:

Lemma 18.

$$C(A) \to (\Pi(x : A), \|U(x)\|) \to \|\Pi(x : A), U(x)\| \tag{57}$$

Proof. Let A be a cardinally finite type, U be a type family on A, and f be a dependent function of type $\Pi(x : A), \|U(x)\|$.

First, since our goal is itself propositionally truncated, we have access to values under truncations: put another way, in the context of proving our goal, we can rely on the fact that A is manifestly Bishop finite. Using the same technique as we did in lemma 11, we can switch from working with dependent functions from A to n-tuples, where n is the cardinality of A. This changes our goal to the following:

$$\mathbf{Tuple}(n, \|\cdot\| \circ U) \to \|\mathbf{Tuple}(n, U)\| \tag{58}$$

Since $\|\cdot\|$ is closed under finite products, this function exists (in fact, using the fact that $\|\cdot\|$ forms a monad, we can recognise this function as `sequenceA` from the `Traversable` class in Haskell). ■

This gets us all of the necessary closure proofs on C.

2.4 Manifest Enumerability

We have now explored quite far in the "less informative" direction. However, all three predicates we have examined are equally *restrictive*: in this section we will see a predicate which is much less restrictive. In particular, this predicate ranges over non-set types.

Definition 26 (Manifest Enumerability)**.** Manifest enumerability is an enumeration predicate like Bishop finiteness or split enumerability with the only difference being a propositionally truncated membership proof.

$$\mathcal{E}(A) :\equiv \Sigma(xs : \mathbf{List}(A)), \Pi(x : A), \|x \in xs\| \tag{59}$$

As a function-based definition, this predicate represents surjections.

Lemma 19. Manifest enumerability is equivalent to a surjection from a finite prefix of the natural numbers.

$$\mathcal{E}(A) \simeq \Sigma(n : \mathbb{N}), (\mathbf{Fin}(n) \twoheadrightarrow A) \tag{60}$$

Proof.

$$\begin{aligned}
\mathcal{E}(A) &\simeq \Sigma(xs : \mathbf{List}(A)), \Pi(x : A), \|x \in xs\| && \text{def. 15 } (\mathcal{E}) \\
&\simeq \Sigma(xs : \mathbf{List}(A)), \Pi(x : A), \|\mathrm{fib}_{\mathrm{snd}(xs)}(x)\| && \text{eqn. 10 } (\in) \\
&\simeq \Sigma(xs : \mathbf{List}(A)), \mathrm{surj}(\mathrm{snd}(xs)) && \text{eqn. 21 (surj)} \\
&\simeq \Sigma(xs : [\![\mathbb{N}, \mathbf{Fin}]\!](A)), \mathrm{surj}(\mathrm{snd}(xs)) && \text{def. 16 (\textbf{List})} \\
&\simeq \Sigma(xs : \Sigma(n : \mathbb{N}), \Pi(i : \mathbf{Fin}(n)), A), \mathrm{surj}(\mathrm{snd}(xs)) && \text{eqn. 9 } ([\![\cdot]\!]) \\
&\simeq \Sigma(n : \mathbb{N}), \Sigma(f : \mathbf{Fin}(n) \to A), \mathrm{surj}(f) && \text{Reassociation of } \Sigma \\
&\simeq \Sigma(n : \mathbb{N}), (\mathbf{Fin}(n) \twoheadrightarrow A) && \text{eqn. 22 } (\twoheadrightarrow)
\end{aligned}$$ ■

2.4.1 Instances for Non-Set Types. The truncation has another very important implication: it means that the predicate doesn't provide decidable equality on the underlying type. Remember, this is how we knew that our previous predicates wouldn't allow for non-set types: because they implied decidable equality, they also implied that all conforming types had homotopy levels of at most 2. This suggests that non-set types like the circle could conform to this finiteness predicate.

Are we doing the homotopy levels starting f

Definition 27 (S^1)**.** The circle, S^1, can be represented in HoTT as a higher inductive type.

$$\begin{aligned} S^1 :\equiv\ & \mathrm{base} : S^1; \\ & \mid \mathrm{loop} : \mathrm{base} \equiv \mathrm{base}; \end{aligned} \tag{61}$$

We will use it here as an example of a non-set type, i.e. a type for which not all paths are equal. This also means that it does not have decidable equality.

Lemma 20. The circle S^1 is manifestly enumerable.

Proof. The support list firstly is a list containing the point constructor for the circle. Since the cover proof is truncated, we need only consider the point constructors of the circle: as such, the cover proof is essentially the same as the one for $\mathcal{E}!(\top)$. ■

2.4.2 Relation To Split Enumerability. It is trivially easy to construct a proof that any split enumerable type is manifest enumerable: we simply truncate the membership proof. Going the other was requires us to extract a non-truncated proof from a truncated one. This proof relies on the following lemma:

Lemma 21. We can "recompute" a truncated proof given a decision over a proof of the same type.

$$\frac{\|A\| \quad \mathbf{Dec}(A)}{A} \tag{62}$$

Proof. We proceed by case-analysis over the decision over A. In the case where A is proven, we are done. In the case where A is disproven, we use lemma 13 to derive impossibility. ■

Lemma 22. A manifestly enumerable type with decidable equality is split enumerable.

Proof. The only difference between manifest enumerability and split enumerability is the membership proof: therefor our goal for this proof is to construct a function of the following type:

$$\|x \in xs\| \to x \in xs \tag{63}$$

Given decidable equality over the type of x.

We do this using the previous recompute lemma: that tells us that all we need to construct is a decision for $x \in xs$, and it will be able to derive the proof itself. Such a decision procedure is not difficult to construct: for any value x and list xs, we proceed through the list xs, testing if x is equal to any of its contents. If it is, we return that we have proven the goal, and that x is indeed present in xs. Otherwise, we know that x cannot be in xs (since we've tested every value), so we return that the goal has been disproven. ■

2.5 Kuratowski Finiteness

The one big missing definition of finiteness to cover is *Kuratowski* finiteness. While it's quite important, it's also quite different from the definitions we've seen so far. It starts with an encoding of the free join semilattice.

Definition 28 (Free Join Semilattice)**.** $\mathcal{K}(A)$ is the free join semilattice, or, alternatively, the type of Kuratowski-finite subsets of A.

$$\begin{aligned}
\mathcal{K}(A) \coloneqq\ & [] && : && \mathcal{K}(A);\\
| \ & \cdot :: \cdot && : && A \to \mathcal{K}(A) \to \mathcal{K}(A);\\
| \ & \text{com} && : && \Pi(x, y : A), \Pi(xs : \mathcal{K}(A)), x :: y :: xs \equiv y :: x :: xs;\\
| \ & \text{dup} && : && \Pi(x : A), \Pi(xs : \mathcal{K}(A)), x :: x :: xs \equiv x :: xs;\\
| \ & \text{trunc} && : && \Pi(xs, ys : \mathcal{K}(A)), \Pi(p, q : xs \equiv ys), p \equiv q;
\end{aligned} \tag{64}$$

We define it as a HIT (definition 13). The first two constructors are point constructors, giving ways to create values of type $\mathcal{K}(A)$. They are also recognisable as the two constructors for finite lists, a type which represents the free monoid.

The next two constructors add extra paths to the type: equations that usage of the type must obey. These extra paths turn the free monoid into the free *commutative* (com) *idempotent* (dup) monoid.

The final constructor enforces that the type $\mathcal{K}(A)$ must be a set.

The Kuratowski finite subset is a free join semilattice (or, equivalently, a free commutative idempotent monoid). More prosaically, $\mathcal{K}$ is the abstract data type for finite sets, as defined in the Boom hierarchy [Boom 1981; Bunkenburg 1994]. However, rather than just being a specification, $\mathcal{K}$ is fully usable as a data type in its own right, thanks to HITs.

Other definitions of $\mathcal{K}$ exist (such as the one in [Frumin et al. 2018]) which make the fact that $\mathcal{K}$ is the free join semilattice more obvious. We have included such a definition in our formalisation, and proven it equivalent to the one above.

Next, we need a way to say that an entire type is Kuratowski finite. For that, we will need to define membership of $\mathcal{K}$.

Definition 29 (Membership of $\mathcal{K}$)**.** Membership is defined by pattern-matching on $\mathcal{K}$. The two point constructors are handled like so:

$$\begin{aligned} x \in \quad [] &:= \bot; \\ x \in y :: ys &:= \|x \equiv y \uplus x \in ys\|; \end{aligned} \tag{65}$$

The com and dup constructors are handled by proving that the truncated form of $\uplus$ is itself commutative and idempotent. The type of propositions is itself a set, satisfying the trunc constructor.

Finally, we have enough background to define Kuratowski finiteness.

Definition 30 (Kuratowski Finiteness)**.**

$$\mathcal{K}^f(A) = \Sigma(xs : \mathcal{K}(A)), \Pi(x : A), x \in xs \tag{66}$$

We also have the following two lemmas, proven in both [Frumin et al. 2018] and our formalisation.

Lemma 23. $\mathcal{K}^f$ is a mere proposition.

Lemma 24. This circle S^1 is Kuratowski finite.

2.5.1 *Relation to Cardinal Finiteness.*

Lemma 25. Cardinal finiteness is equivalent to Kuratowski finiteness over a discrete set.

$$C(A) \simeq \mathcal{K}^f(A) \times \mathrm{Discrete}(A) \tag{67}$$

This proof is constructed by providing a pair of functions: one from $C(A)$ to $\mathcal{K}^f(A) \times \mathrm{Discrete}(A)$, and one the other way. This pair implies an equivalence, because both source and target are propositions. The actual functions themselves are proven in our formalisation, as well as in [Frumin et al. 2018].

3 TOPOS

In this section we will examine the categorical interpretation of finite sets. In particular, we will prove that decidable Kuratowski finite types form a Π-pretopos. A lot of the work for this proof has been done already: in Theorem 25 we saw that Kuratowski finite types were equivalent to Cardinally finite types. We will use the latter definition implementation-wise from now on, as it is slightly easier to work with: CuTT's transport means we can do this without loss of generality.

3.1 Categories in HoTT

3.2 Closure and the Category of Sets

3.3 The Absence of the Subobject Classifier

3.4 Closure

For the first three closure proofs, we only consider split enumerability: as it is the strongest of the finiteness predicates, we can derive the other closure proofs from it.

3.5 The Category of Finite Sets

HoTT and CuTT seem to be especially suitable settings for formalisations of category theory. The univalence axiom in particular allows us to treat categorical isomorphisms as equalities, saving us from the dreaded "setoid hell".

We follow [Univalent Foundations Program 2013, chapter 9] in its treatment of categories in HoTT, and in its proof that sets do indeed form a category. We will first briefly go through the construction of the category *Set*, as it differs slightly from the usual method in type theory.

First, the type of objects and arrows:

$$\mathrm{Obj}_{Set} \coloneqq \Sigma(x : \mathbf{Type}), \mathrm{isSet}(x) \tag{68}$$

$$\mathrm{Hom}_{Set}(x, y) \coloneqq \mathrm{fst}(x) \to \mathrm{fst}(y) \tag{69}$$

As the type of objects makes clear, we have already departed slightly from the simpler $\mathrm{Obj}_{Set} \coloneqq \mathbf{Type}$ way of doing things: of course we have to, as HoTT allows non-set types. Furthermore, after proving the usual associativity and identity laws for composition (which are definitionally true in this case), we must further show $\mathrm{isSet}(\mathrm{Hom}_{Set}(x, y))$; even then we only have a precategory.

To show that *Set* is a category, we must show that categorical isomorphisms are equivalent to equivalences. In a sense, we must give a univalence rule for the category we are working in.

We have provided formal proofs that *Set* does indeed form a category, and the following:

Theorem 26 (The Category of Finite Sets)**.** Finite sets form a category in HoTT when defined like so:

$$\begin{aligned} \mathrm{Obj}_{FinSet} &\coloneqq \Sigma(x : \mathbf{Type}), C(x) \\ \mathrm{Hom}_{FinSet}(x, y) &\coloneqq \mathrm{fst}(x) \to \mathrm{fst}(y) \end{aligned} \tag{70}$$

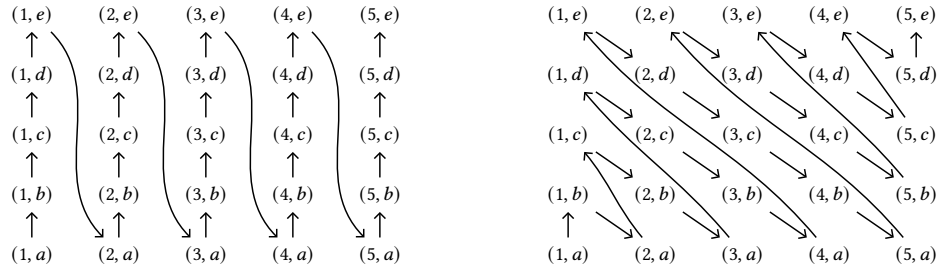
3.6 The Π-pretopos of Finite Sets

For this proof, we follow again the proof that *Set* forms a ΠW-pretopos from [Univalent Foundations Program 2013, chapter 10] and [Rijke and Spitters 2015]. The difference here is that clearly we do not have access to W-types, as they would permit infinitary structures.

We first must show that *Set* has an initial object and finite, disjoint sums, which are stable under pullback. We also must show that *Set* is a regular category with effective quotients. We now have a pretopos: the presence of Π types make it a Π-pretopos.

We have proven the above statements for both *Set* and *FinSet*. As far as we know, this is the first formalisation of either.

Theorem 27. The category of finite sets, *FinSet*, forms a Π-pretopos.



(a) Depth-First (b) Breadth-First

Fig. 3. Two possible products for the sets $[1 \dots 5]$ and $[a \dots e]$

4 COUNTABLY INFINITE TYPES

In the previous sections we saw different flavours of finiteness which were really just different flavours of relations to **Fin**. In this section we will see that we can construct a similar classification of relations to $\mathbb{N}$, in the form of the countably infinite types.

4.1 Two Countable Types

The two types for countability we will consider are analogous to split enumerability and cardinal finiteness. The change will be a simple one: we will swap out lists for streams.

Definition 31 (Streams)**.**

$$\mathbf{Stream}(A) :\equiv (\mathbb{N} \to A) \simeq [\![\top, \mathrm{const}(\mathbb{N})]\!] \tag{71}$$

Definition 32 (Split Countability)**.**

$$\aleph_0!(A) :\equiv \Sigma(xs : \mathbf{Stream}(A)), \Pi(x : A), x \in xs \tag{72}$$

This type is definitionally equal to it surjection equivalent $(\mathbb{N} \twoheadrightarrow! A)$. We construct the unordered, propositional version of the predicate in much the same way as we constructed cardinal finiteness.

Definition 33 (Countability)**.**

$$\aleph_0(A) :\equiv \|\aleph_0!(A)\| \tag{73}$$

From both of these types we can derive decidable equality.

Lemma 28. Any countable type has decidable equality.

4.2 Closure

We know that countable infinity is not closed under the exponential (function arrow), so the only closure we need to prove is Σ to cover all of what's left.

Theorem 29. Split countability is closed under Σ.

We know that countable infinity is not closed under the exponential (function arrow), so the only closure we need to prove is Σ to cover all of what's left. To do this we have to take a slightly different approach to the functions we defined before. Figure 3 illustrates the reason why: previously, we used the depth-first product pairing for each support list. This diverges if the first list is infinite, never exploring anything other than the first element in the second list. Instead, we use here the cantor pairing function, which performs a breadth-first search of the pairings of both lists.

Finally, while we have lost certain closure proofs by allowing for infinite types, we also *gain* some: in particular the Kleene star.

Theorem 30. Split countability is closed under Kleene star.

$$\aleph_0!(A) \to \aleph_0!(\mathbf{List}(A)) \tag{74}$$

Again, this proof requires a particular pattern to ensure productivity. The pattern here builds an intermediate stream $\mathcal{KV}$ of non-empty lists from the input support stream xs, which is subsequently flattened.

$$\mathcal{KV}_i \coloneqq \left[\left[xs_{j-1} \mid j \in js\right] \mid js \in \mathbf{List}(\mathbb{N}); \mathrm{sum}(js) = i; 0 \notin js\right] \tag{75}$$

5 SEARCH

5.1 Omniscience

Definition 34 (Limited Principle of Omniscience)**.** For any type A and predicate P on A, the limited principle of omniscience [Myhill 1972] is as follows:

$$(\Pi(x : A), \mathbf{Dec}(P(x))) \to \mathbf{Dec}\,(\Sigma(x : A), P(x)) \tag{76}$$

In other words, for any decidable predicate the existential quantification of that predicate is also decidable.

The limited principle of omniscience is non-constructive, but individual types can themselves satisfy omniscience. In particular, cardinal finite types are omniscient.

There is also a universal form of omniscience, which we call exhaustibility.

Definition 35 (Exhaustibility)**.** We say a type A is exhaustible if, for any decidable predicate P on A, the universal quantification of the predicate is decidable.

$$(\Pi(x : A), \mathbf{Dec}(P(x))) \to \mathbf{Dec}\,(\Pi(x : A), P(x)) \tag{77}$$

All of the finiteness predicates we have seen imply exhaustibility. Omniscience is stronger than exhaustibility, as we can derive the latter from the former. All of the ordered finiteness predicates imply omniscience. For the unordered finiteness definitions, we have omniscience for prop-valued predicates.

5.2 Automating Proofs

One use for above constructions is the automation of certain proofs. In [Firsov and Uustalu 2015], which uses a similar approach to ours, the Pauli group is used as an example.

```
data Pauli : Type₀ where X Y Z I : Pauli
```

As Pauli has 4 constructors, n-ary functions on Pauli may require up to 4^n cases, making even simple proofs prohibitively verbose.

The alternative is to derive the things we need from omniscience, itself derived from a finiteness predicate. For proof search, the procedure is a well-known one in Agda [Devriese and Piessens 2011]: we ask for the result of a decision procedure as an *instance argument*, which will demand computation during typechecking. Our addition to this technique is a way to handle multiple arguments based on fully level-polymorphic dependent currying and uncurrying, building on [Allais 2019].

```
assoc·· : ∀ x y z → (x · y) · z ≡ x · (y · z)
assoc·· = ∀ⁿ 3 λ x y z → (x · y) · z ≟ x · (y · z)
```

Finally, we can derive decidable equality on functions over finite types. We can also use functions in our proof search. Here, for instance, is an automated procedure which finds the not function on **Bool**, given a specification.

```
not-spec : Σ[ f ∶ (Bool → Bool) ] (f ∘ f ≡ id) × (f ≢ id)
not-spec = ∃ⁿ 1 λ f → (f ∘ f ≟ id) &&-dec ¬? (f ≟ id)
```

Cubical Type Theory. [Cohen et al. 2016]

Cubical Agda. [Vezzosi et al. 2019]

Constructive Finiteness.

- First paper on the topic, defines 4 notions of finiteness (split enumerability, there called enumerated, bounded, Noetherian, streamless): [Coquand and Spiwack 2010]
- More exploration of Noetherianness [Firsov et al. 2016]
- More exploration of streamless sets [Parmann 2015] (in particular closure under product).
- Paper exploring programming with finite sets for e.g. proof search [Firsov and Uustalu 2015] (basically only enumerable sets though, only in MLTT)
- Finite sets in Homotopy Type Theory, especially Kuratowski [Frumin et al. 2018] (but no finite function arrows).
- Kuratowski's original paper on finiteness [Kuratowski 1920].
- [Smolka and Stark 2016].

Sets/Toposes.

- Paper that sets in HoTT form a topos (under certain conditions etc) [Rijke and Spitters 2015]. This paper is adapted into a chapter in the HoTT book.
- Category theory in cubical Agda [Iversen 2018].
- Topos from cardinal finite [Henry 2018].
- Category of finite sets [Solov'ev 1983].

Species.

- Brent Yorgey's thesis [Yorgey 2014].
